PREFACE

This report was prepared under Project No. 710C10, *Computationally Efficient Algorithms for Subspace Estimation*, principal investigator Alain C. Barthelemy, Code 2151, NUWC Detachment New London.

The technical reviewer for this report was R. R. Kneipfer, Code 214, NUWC Detachment New London.

The author is grateful to Dr. W. I. Roderick for his funding of the original project, T. C. Choinski and M. H. Leonhardt for their guidance and encouragement during the preparation of the manuscript, and Dr. N. L. Owsley of NUWC Detachment New London and Dr. P. K. Willett from the University of Connecticut for their significant contributions to the research.

REVIEWED AND APPROVED: 7 NOVEMBER 1993

F. J. Kingsbury
Head, Submarine Sonar Department

13. ABSTRACT (Maximum 200 words) This report presents an algorithm for the estimation of noise correlations for an array of sensors. The algorithm assumes a mixed spectra model composed of discrete sinusoidal sources and continuous noise components. A spatial AR process models the continuous component. Previous methods use spatial AR models with real coefficients, restricting the utility of the model to noise sources that impinge on an array at broadside. The complex formulation presented here solves the general problem of arbitrarily oriented noise sources. The technique uses a gradient algorithm for maximization of a likelihood functional to solve for the complex AR coefficients. Once the algorithm determines the noise covariance matrix, prewhitening techniques allow detection of threshold sources. The multiple signal classification (MUSIC) direction finder when applied to the prewhitened observed correlation matrix illustrates the usefulness in detecting low signal-to-noise ratio (SNR) sources. Computational examples used the standardized test case (STC), a realistic model with a challenging range of SNR and difficult source locations.

PREWHITENING OF COLORED NOISE FIELDS FOR DETECTION OF THRESHOLD SOURCES

INTRODUCTION

High resolution direction finding methods such as Multiple Signal Classification (MUSIC),¹ Enhanced Minimum Variance Distortionless Response (EMVDR),² and Minimum Norm (Min-Norm)³ compute angular response as a function of cosine of bearing angle. These methods associate peaks in the response function with source locations, providing direction of arrival estimates. A response peak that does not correspond to an existing source indicates a false alarm. Rooting techniques for direction finding such as ROOT-MUSIC,⁴ Estimation of Signal Parameters Via Rotational Invariance Techniques (ESPRIT),⁵ and the Pisarenko Harmonic Decomposition (PHD)⁶ provide source locations directly, without computation of a response function, by constructing a polynomial whose roots correspond to arrival angles. Any angle that does not correspond to an existing source indicates a false alarm. Typically, these algorithms provide a large set of candidate arrival angles that includes true source locations and spurious ones. Although methods exist for determining the true source locations from the candidate set,⁷ they require an accurate set of candidate angles with as few false alarms as possible.

Both types of direction finders exhibit high false alarm rates in the presence of spatially colored ambient noise. In their traditional model formulation, direction finders assume that only spatially white noise exists. When an extended or continuous colored noise is present in the acoustic field, low SNR or threshold sources may be obscured from detection. Also, the estimate of a source location for a source that exists within the spatial bandwidth of the colored noise may be biased. Thus, in the presence of known nonwhite noise, high false alarm performance necessitates the use of prewhitening algorithms.⁸ Direction finders also require a reliable estimate of the number of sources present in the observed noise field.⁸ Because nonwhite noise skews or inflates this estimate, prewhitening is required.

MOTIVATION FOR PREWHITENING

Define \mathbf{x} as the N -dimensional sensor output data vector from an N -element uniform line array. Denote the covariance matrix of \mathbf{x} by

$$\mathbf{R} = E[\mathbf{x}\mathbf{x}^H], \quad (1)$$

where

$$\mathbf{x}^T = [x_1 \ x_2 \ \dots \ x_N], \quad (2)$$

$E[\cdot]$ represents the expectation operator, and H denotes complex conjugate transpose. Model \mathbf{R} with the following structure⁹

$$\mathbf{R} = \sigma_{DS}^2 \mathbf{P} + \sigma_{ES}^2 \mathbf{Q} + \sigma_0^2 \mathbf{I}_N, \quad (3)$$

where \mathbf{P} corresponds to the discrete source (DS) component, \mathbf{Q} to the extended source (ES) component (in this case colored noise), and \mathbf{I}_N (an N by N identity matrix) to the component due to uncorrelated noise. Normalize \mathbf{P} and \mathbf{Q} so that each trace equals N . The three variances, σ_{DS}^2 , σ_{ES}^2 , and σ_0^2 , represent the power at a single sensor due to discrete sources, extended sources, and uncorrelated noise, respectively.

Define the discrete source component \mathbf{P} corresponding to $q \leq N$ discrete angular sources at θ_i , $i = 1, 2, \dots, q$, as⁹

$$\mathbf{P} = \mathbf{D}\mathbf{C}\mathbf{D}^H, \quad (4)$$

where the N by q steering matrix $\mathbf{D} = [\mathbf{d}_1 \ \mathbf{d}_2 \ \dots \ \mathbf{d}_q]$ contains the i -th column

$$\mathbf{d}_i^T = [1 \ e^{-j\mathbf{k}_i d} \ e^{-j\mathbf{k}_i (2d)} \ \dots \ e^{-j\mathbf{k}_i (N-1)d}], \quad (5)$$

and the wavenumber of the i -th source at θ_i is

$$\mathbf{k}_i = \frac{2\pi}{\lambda} \cos(\theta_i). \quad (6)$$

The factor d is the nominal spacing between sensors, given as a fraction of the wavelength λ . Write the above expression as a function of angular frequency equal to the cosine of the bearing angle of interest θ , with $0 \leq \theta \leq \pi$. Assume a diagonal source coherence matrix C so that no correlation exists between sources. A thin spike or delta function illustrates the spatial density of a discrete source at bearing angle θ .

EXAMPLE 1: EXTENDED SOURCE ENERGY SPECTRUM

The angular energy spectrum of an extended source at bearing angle θ affects a spatial bandwidth around the angle θ .

Compute the spatial density of an arbitrary extended source modeled as a first order autoregressive (AR) process with coefficient $a_1 = -0.7$ steered to 45 degrees. Figure 1 depicts the spatial density.

Figure 1. Extended Source Spectrum

Model the P extended sources in component Q as the sum of L -th order AR spatial processes Q_i utilizing the Gohberg Formula¹⁰ with complex coefficients $a_{i,j}$, scaled by a factor α_i , $i = 1, 2, \dots, P$, as follows:

$$\mathbf{Q} = \sum_{i=1}^P \alpha_i \mathbf{Q}_i, \quad (7)$$

$$\mathbf{Q}_i^{-1} = \frac{1}{\sigma_{ES}^2} (\mathbf{A}_{i,1} \mathbf{A}_{i,1}^H - \mathbf{A}_{i,3} \mathbf{A}_{i,3}^H), \quad (8)$$

$$\sum_{i=1}^P \alpha_i = 1, \quad (9)$$

with $\mathbf{A}_{i,1}$ and $\mathbf{A}_{i,3}$, which are the N by N lower triangular Toeplitz matrices

$$\mathbf{A}_{i,1} = \begin{bmatrix} 1 & & & & & & & \\ a_{i,1} & \ddots & & & & & & \\ a_{i,2} & \ddots & \ddots & & & & & \\ \vdots & \ddots & \ddots & \ddots & & & & \\ a_{i,L} & \ddots & \ddots & \ddots & \ddots & & & \\ 0 & & a_{i,L} & \cdots & a_{i,2} & a_{i,1} & 1 & \end{bmatrix} \quad \mathbf{A}_{i,3} = \begin{bmatrix} & & & & & & 0 \\ & & & & & & \\ & & & & & & \\ a_{i,L} & & & & & & \\ \vdots & & & & & & \\ a_{i,2} & & & & & & \\ a_{i,1} & a_{i,2} & \cdots & a_{i,L} & & & \end{bmatrix}. \quad (10)$$

A useful description of a complex AR parameter is the polar form, consisting of magnitude and steering angle. Given the magnitude of an AR coefficient, a_i , and a steering angle, θ , compute the equivalent complex coefficient \tilde{a}_i as

$$\tilde{a}_i = a_i e^{j2\pi d \cos(\theta)}. \quad (11)$$

Later in this report when the standardized test case (STC)⁹ is used to test the prewhitening algorithm, the expression in equation (11) will be useful.

EXAMPLE 2: COMPLEX AR COEFFICIENT

For an array with quarter-wavelength sensor spacing ($d = 0.25$), model the extended source from example 1 by computing the equivalent complex AR coefficient as follows:

$$a_1 = -0.7, \quad (12)$$

$$\theta = 45 \text{ degrees} , \quad (13)$$

and

$$\begin{aligned} \tilde{a}_1 &= -0.7e^{j2\pi(0.25)\cos(45)} \\ &= -0.3108 - 0.6272i . \end{aligned} \quad (14)$$

While figure 1 has illustrated the spatial energy density for this process, figure 2 shows a pole plot of the coefficient \tilde{a}_1 .

Figure 2. Pole Plot for Example 2

EXAMPLE 3: MUSIC IN A COLORED BACKGROUND NOISE

Now, consider an example that illustrates the degradation in performance when the MUSIC direction finder is used in a nonwhite background spectrum environment.

Given an eight sensor array with quarter-wavelength sensor spacing and a 0-dB extended source from example 2, inject two discrete sources into the observed noise field:

Discrete source 1: 30 degrees, SNR = -3 dB

Discrete source 2: 70 degrees, SNR = -19 dB.

Compare the MUSIC spectra for the prewhitened and non-prewhitened cases. For the MUSIC computation, assume the presence of $q = 3$ sources.

In figure 3, the dotted vertical lines represent the true direction of arrival (DOA) angles. The dashed line corresponds to the prewhitened MUSIC spectra. The non-prewhitened case exhibits a strong bias due to the extended source at 45 degrees. The stronger extended source obscures the low SNR source at 70 degrees.

Figure 3. MUSIC Spectra for Example 3

METHOD OF PREWHITENING

Define $\tilde{\mathbf{x}}$ as an N-dimensional vector whose covariance matrix is given by

$$\begin{aligned}\tilde{\mathbf{R}} &= E[\tilde{\mathbf{x}}\tilde{\mathbf{x}}^H] \\ &= \mathbf{R} - \sigma_0^2 \mathbf{I}_N \\ &= \sigma_{DS}^2 \mathbf{P} + \sigma_{ES}^2 \mathbf{Q},\end{aligned}\tag{15}$$

where $\tilde{\mathbf{x}} = [\tilde{x}_1 \ \tilde{x}_2 \ \dots \ \tilde{x}_N]^T$. Note that $\tilde{\mathbf{R}}$ is the covariance matrix in the absence of uncorrelated noise and can be estimated by using the smallest eigenvalue of \mathbf{R} as an estimate of σ_0^2 .

If \mathbf{L}_{ES} is the lower triangular matrix Cholesky factor given by

$$\mathbf{L}_{ES} \mathbf{L}_{ES}^H = \sigma_{ES}^2 \mathbf{Q},\tag{16}$$

define a prewhitened snapshot vector as

$$\mathbf{x}_{PW} = \mathbf{L}_{ES}^{-1} \tilde{\mathbf{x}}.\tag{17}$$

The covariance matrix \mathbf{R}_{PW} of the prewhitened vector then contains a purely white spatial noise density,

$$\begin{aligned}\mathbf{R}_{PW} &= E[\mathbf{x}_{PW} \mathbf{x}_{PW}^H] \\ &= \mathbf{L}_{ES}^{-1} \tilde{\mathbf{R}} \mathbf{L}_{ES}^{-H} \\ &= \sigma_{DS}^2 \mathbf{L}_{ES}^{-1} \mathbf{P} \mathbf{L}_{ES}^{-H} + \sigma_{ES}^2 \mathbf{L}_{ES}^{-1} \mathbf{Q} \mathbf{L}_{ES}^{-H} \\ &= \sigma_{DS}^2 \mathbf{L}_{ES}^{-1} \mathbf{P} \mathbf{L}_{ES}^{-H} + \sigma_{ES}^2 \mathbf{L}_{ES}^{-1} \frac{\mathbf{L}_{ES} \mathbf{L}_{ES}^H}{\sigma_{ES}^2} \mathbf{L}_{ES}^{-H} \\ &= \sigma_{DS}^2 \mathbf{L}_{ES}^{-1} \mathbf{P} \mathbf{L}_{ES}^{-H} + \mathbf{I}_N,\end{aligned}\tag{18}$$

where

$$\mathbf{L}_{ES}^{-H} = (\mathbf{L}_{ES}^H)^{-1}.\tag{19}$$

The algorithm for prewhitening the measured matrix $\hat{\mathbf{R}}$ minimizes a likelihood functional¹¹ to obtain an estimate of \mathbf{Q} .

THE LIKELIHOOD FUNCTIONAL

Following the development in reference (11), assume we are given K array data snapshots in a sequence,

$$\{\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_K\}, \quad (20)$$

with covariance \mathbf{R} . Form the estimate¹² of \mathbf{R} as

$$\hat{\mathbf{R}} = \frac{1}{K} \sum_{k=0}^{K-1} \mathbf{x}_k \mathbf{x}_k^H. \quad (21)$$

The likelihood functional relates the estimate $\hat{\mathbf{R}}$ to an assumed covariance structure \mathbf{R} . To aid in the derivation, first assume that the true covariance

$$\mathbf{R} = \mathbf{P} + \lambda \mathbf{I}_N \quad (22)$$

corresponds to the white noise case, and omit the scale factors for brevity. The factor λ equals a positive scalar parameter. The matrix \mathbf{P} equals an unknown covariance matrix of rank q . Although methods¹³⁻¹⁵ exist for the computation of q , the number of sources present assume that q represents a known quantity. The function

$$f(\{\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_K\} / \lambda, \mathbf{P}) = \frac{1}{\pi^{KN} |\mathbf{R}|^K} e^{-K \text{trace}(\hat{\mathbf{R}} \mathbf{R}^{-1})} \quad (23)$$

represents the conditional density for the complex Gaussian sequence \mathbf{x}_i , $i = 1, 2, \dots, K$, with covariance \mathbf{R} conditioned on (λ, \mathbf{P}) and $||$ being the determinant operator. The function $\text{trace}(\mathbf{A})$ sums the diagonal elements of matrix \mathbf{A} . The problem now involves seeking the values for (λ, \mathbf{P}) that maximize this likelihood. To express the log-likelihood as a functional in terms of the eigenvalues of $\hat{\mathbf{R}}$, $\hat{\lambda}_1 \geq \hat{\lambda}_2 \geq \dots \geq \hat{\lambda}_N$, define

$$\bar{\lambda}_{GM}(q) = \left(\prod_{i=q+1}^N \hat{\lambda}_i \right)^{\frac{1}{N-q}} \quad (24)$$

and

$$\bar{\lambda}_{AM}(q) = \frac{1}{N-q} \left(\sum_{i=q+1}^N \hat{\lambda}_i \right) \quad (25)$$

as the geometric and arithmetic means, respectively, of the $N-q$ lowest eigenvalues of $\hat{\mathbf{R}}$. As shown in reference (11), we can then write

$$\begin{aligned} & \max \ln(f(\{\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_K\} / \lambda, \mathbf{P})) \\ &= K \left(-N \ln(\pi) - N - \ln(|\hat{\mathbf{R}}|) + \sum_{i=q+1}^N \ln(\hat{\lambda}_i) - (N-q) \ln(\bar{\lambda}_{AM}(q)) \right). \end{aligned} \quad (26)$$

Maximizing the likelihood is equivalent to maximizing the functional:

$$L_q(\mathbf{Q}) = (N-q) \left(\ln(\bar{\lambda}_{GM}(q)) - \ln(\bar{\lambda}_{AM}(q)) \right). \quad (27)$$

For the spatially nonwhite case, use the form

$$\tilde{\mathbf{R}} = \mathbf{P} + \lambda \mathbf{Q} \quad (28)$$

for the assumed true covariance matrix. As in the preceding section, decompose \mathbf{Q} into Cholesky triangular factors,

$$\mathbf{Q} = \mathbf{L}\mathbf{L}^H, \quad (29)$$

and form the prewhitened covariance matrix

$$\mathbf{R}_{PW} = \mathbf{L}^{-1} \tilde{\mathbf{R}} \mathbf{L}^{-H}. \quad (30)$$

It can then be shown (see reference (11)) that the likelihood functional conditional to the noise covariance \mathbf{Q} with q sources is

$$L_q(\mathbf{Q}) = (N - q) \left(\ln \left(\bar{\lambda}_{\text{WGM}}(q) \right) - \ln \left(\bar{\lambda}_{\text{WAM}}(q) \right) \right), \quad (31)$$

where $\bar{\lambda}_{\text{WGM}}(q)$ and $\bar{\lambda}_{\text{WAM}}(q)$ correspond to the geometric and arithmetic means, respectively, of the eigenvalues of the prewhitened covariance matrix \mathbf{R}_{pw} . The geometric and arithmetic means realize equality only for the case of equality between the $N-q$ lowest eigenvalues. The equality of the $N-q$ smallest eigenvalues represents a flat, spatially white noise spectrum, and in this case, $L_q(\mathbf{Q})$ equals zero.

MAXIMIZATION OF THE LIKELIHOOD FUNCTIONAL - LE CADRE'S TECHNIQUE

The prewhitening problem next becomes one of maximizing $L_q(\mathbf{Q})$ relative to the coefficients a_1, a_2, \dots, a_L parameterizing the noise covariance matrix \mathbf{Q} . Accomplish the maximization by an iterative gradient algorithm¹¹ at step k with parameter vector

$$\mathbf{A}_k^T = (\sigma_k^2, a_1^k, a_2^k, \dots, a_L^k) \quad (32)$$

and general form

$$\mathbf{A}_{k+1} = \mathbf{A}_k - \rho_0 \mathbf{G}_k, \quad (33)$$

where ρ_0 defines a step size, in this case constant, and \mathbf{G}_k defines the gradient vector. Computation of the i -th element of \mathbf{G}_k consists of calculating

$$G_k(i) = \frac{\partial}{\partial a_i^k} \lambda_j^k \quad (34)$$

for $i = 1, 2, \dots, L$. Figure 4 expresses a functional relationship between the eigenvalues of the prewhitened covariance matrix, the likelihood function, and the AR coefficients. The algorithm seeks to find the maximum of the likelihood functional surface parameterized by the AR coefficients.

Figure 4. Relation of Likelihood Functional to ARMA parameters

EXAMPLE 4: LIKELIHOOD FUNCTIONAL SURFACE CONTOUR

Given the acoustic field from example 3, plot the maximization surface contour of $L_q(Q)$ in figure 5 as a function of the real and imaginary parts of the coefficient \tilde{a}_1 .

Figure 5. Maximization Surface Contour Plot of $L_q(Q)$

Clearly, the maximum value of $L_q(Q)$ occurs at the exact value of the coefficient computed in example 2.

Computation of the gradient vector reduces to

$$G_k(i) = \frac{\partial}{\partial a_i^k} \lambda_j^k \quad (35)$$

for $i = 1, 2, \dots, L$ and $j = 1, 2, \dots, N$.

LEMMAS: EIGENVALUES OF PREWHITENED COVARIANCE MATRIX

The following lemmas represent intermediate steps in this computation.

Lemma 1: The eigenvalues of $R_{pw,k}$ equal the eigenvalues of $Q_k^{-1} \hat{R}$.

Proof: To compute the eigenvalues $\lambda_1, \lambda_2, \dots, \lambda_N$ of the N by N matrix A , solve

$$|A - \lambda I_N| = 0. \quad (36)$$

With this fact and defining

$$L_k L_k^H = Q_k^{-1}, \quad (37)$$

then

$$\begin{aligned} & |Q_k^{-1} \hat{R} - \lambda I_N| \\ &= |L_k L_k^H \hat{R} - \lambda I_N| \\ &= |L_k^H \hat{R} L_k - \lambda I_N| \\ &= |R_{pw,k} - \lambda I_N|. \end{aligned} \quad (38)$$

Lemma 2: If $\hat{R} = TT^H$, the eigenvalues of $R_{pw,k}$ equal the eigenvalues of $T^H Q_k^{-1} T$.

Proof:

$$\begin{aligned}
& |\mathbf{Q}_k^{-1} \hat{\mathbf{R}} - \lambda \mathbf{I}_N| \\
&= |\mathbf{Q}_k^{-1} \mathbf{T} \mathbf{T}^H - \lambda \mathbf{I}_N| \\
&= |\mathbf{T}^H \mathbf{Q}_k^{-1} \mathbf{T} - \lambda \mathbf{I}_N|.
\end{aligned} \tag{39}$$

Therefore the computation of $\partial \lambda_j^k / \partial a_i^k$ reduces to the computation of $\partial \mu_j^k / \partial a_i^k$, the partial derivatives of the eigenvalues of the Hermitian matrix $\mathbf{T}^H \mathbf{Q}_k^{-1} \mathbf{T}$. Since the AR coefficients form an explicit function for \mathbf{Q}_k^{-1} , this reduction represents an important result.¹¹ Additionally, use the following classical result for an N by N Hermitian matrix \mathbf{A} ($\mathbf{A} = \mathbf{A}^H$) with simple eigenvalues λ_j and associated eigenvectors \mathbf{v}_j :

$$\frac{\partial}{\partial a_i} \lambda_j = \mathbf{v}_j^* \frac{\partial}{\partial a_i} \mathbf{A} \mathbf{v}_j. \tag{40}$$

Equation (40) derives from the eigenstructure definition

$$\mathbf{A} = \sum_{j=1}^N \mathbf{v}_j \lambda_j \mathbf{v}_j^H. \tag{41}$$

ALGORITHM FOR MAXIMIZATION OF THE LIKELIHOOD FUNCTIONAL BY COMPUTATION OF THE GRADIENT VECTOR \mathbf{G}_k

Continuing to parallel the development in reference (11), we employ the above definitions and lemmas to write the algorithm as follows.

1. Compute partial derivatives of \mathbf{Q}_k^{-1} relative to the complex AR parameters a_i :

$$\Delta_i^k = \frac{\partial \mathbf{Q}_k^{-1}}{\partial a_i} = \frac{2}{\sigma_{\text{ES}}^2} \left(\mathbf{A}_{1,k}(\mathbf{Z}^i)^T - \mathbf{A}_{3,k}(\mathbf{Z}^{N-i})^T \right) \tag{42}$$

for $i = 0, 1, \dots, L$.

(See appendix A for derivation of this expression and the definition of \mathbf{Z}^i .)

2. Compute derivative matrices:

$$\begin{aligned}\Delta_i^k &= \frac{\partial}{\partial a_i} (\mathbf{T}^H \mathbf{Q}^{-1} \mathbf{T}) \\ &= \mathbf{T}^H \Delta_i^k \mathbf{T}\end{aligned}\tag{43}$$

recalling that

$$\hat{\mathbf{R}} = \mathbf{T} \mathbf{T}^H.\tag{44}$$

3. Calculate partial derivatives of the simple eigenvalues of $\mathbf{R}_{pw, k}$:

$$\frac{\partial}{\partial a_i} \lambda_j^k = (\mathbf{u}_j^k)^H \Delta_i^k \mathbf{u}_j^k,\tag{45}$$

where \mathbf{u}_j^k represents an eigenvector associated to the eigenvalue λ_j^k of $\mathbf{T}^H \mathbf{Q}^{-1} \mathbf{T}$. Compute this eigenstructure with conventional or reduced complexity algorithms.¹⁶⁻²⁵

4. Calculate the components of the gradient vector \mathbf{G}_k :

$$\mathbf{G}_k(i) = \sum_{j=q+1}^N \left(\frac{\frac{\partial}{\partial a_i} \lambda_j^k}{\lambda_j^k} \right) - \frac{\sum_{j=q+1}^N \frac{\partial}{\partial a_i} \lambda_j^k}{\bar{\lambda}_{AM}(q)},\tag{46}$$

where

$$\bar{\lambda}_{AM}(q) = \frac{1}{N-q} \left(\sum_{j=q+1}^N \lambda_j^k \right).\tag{47}$$

5. Select step size to ensure adequate convergence rate.

Although methods¹¹ exist for updating ρ_0 , assume a fixed step size arrived at by trial-and-error.

PERFORMANCE METRICS

Four performance metrics will be used to evaluate algorithm performance:

1. Compute a pole plot of the AR coefficients by generating one at each iteration of gradient algorithm to view convergence trajectory.
2. Compute the cosine of the angle between the estimated covariance Q_{EST} and the true covariance Q_{TRUE} :

$$\cos(Q_{EST}, Q_{TRUE}) = \frac{\text{trace}(Q_{EST} Q_{TRUE})}{\sqrt{\text{trace}(Q_{EST} Q_{EST}) \text{trace}(Q_{TRUE} Q_{TRUE})}} \quad (48)$$

A cosine close to 1 implies collinearity.

3. Compute the AR spatial density for estimated coefficients:

$$S(z) = \frac{1}{A(z)A^*(z)}, \quad (49)$$

where " * " corresponds to the complex conjugate and

$$A(z) = a_0 + a_1 z + a_2 z^2 + \dots + a_L z^L \quad (50)$$

$$z = e^{-j2\pi d \cos(\theta)} \quad (51)$$

4. Compute the MUSIC^{1, 26} bearing response for prewhitened case:

$$P_{MUSIC}(\theta) = \frac{1}{e^H(\theta) \left(\sum_{j=q+1}^N u_j u_j^H \right) e(\theta)}, \quad (52)$$

where

$$e^T(\theta) = [1 e^{j2\pi d \cos(\theta)} e^{j4\pi d \cos(\theta)} \dots e^{j2(N-1)\pi d \cos(\theta)}] \quad (53)$$

and u_j represents an eigenvector of the prewhitened covariance matrix R_{PW} .

THE STC SIMULATIONAL DATA

To evaluate the effectiveness of the proposed method, use the STC,⁹ a realistic model with a challenging range of SNR and difficult source locations. The STC employs quarter-wavelength sensor spacing. Figure 6 depicts the STC source locations graphically and table 1 enumerates the relative source strengths.

Figure 6. The STC

Table 1. The STC

	BEARING θ (DEGREES)	COS(θ)	AR PARAMETER	SNR (dB)
DISCRETE SOURCES				
1	105	-0.26	-	-20
2	90	0	-	-3
3	85	0.09	-	-3
4	70	0.34	-	0
5	45	0.71	-	-14
EXTENDED SOURCES				
1	0	1	-0.7j	0
2	135	-0.71	-0.4263+0.8602j	-27

RESULTS OF SIMULATION

Assume an $L = 4$ AR model and initialize the algorithm with parameter vector

$$\mathbf{A}^T = (1, 0, 0, 0, 0) . \quad (54)$$

Run the algorithm for 25 iterations with step size $\rho_0 = -0.025$. Set q equal to the number of signal eigenvalues, 7, for the prewhitener and for MUSIC. Assume a known noise floor σ_0^2 .

Figures 7 through 10 illustrate the results of the Le Cadre algorithm on the STC. The great disparity in SNR for the two extended sources (ES) causes the algorithm to prewhiten only the noise associated with ES 1 at 0 degrees. Although a fourth-order AR process attempts to model the sum of two first order processes, in this case, a first-order model suffices. The MUSIC spectrum shows that although the prewhitening of ES 1 allows detection of the discrete source at 45 degrees, it also causes the promotion of a weak second extended source, ES 2. The number of assumed sources plays an important role in the detection of ES 2; indeed if $q = 5$, the peak at 135 degrees disappears. Attempts to prewhiten the small source at 135 degrees with a second pass of the algorithm fail because of the nature of the remaining eigenvalues of the prewhitened \mathbf{R} .

Figure 7. Pole Plot for STC

Figure 8. Cosine Metric for STC

Figure 9. Noise Spatial Density for STC

Figure 10. MUSIC Response for STC

Figure 11 depicts the eigenvalues associated with the STC. The solid line corresponds to the non-prewhitened case and the dotted line corresponds to the case following the 25th iteration of the algorithm. The dashed line represents the eigenvalues omitting the two extended sources entirely. To visualize the failure of the attempted second pass of the algorithm, recall that the likelihood functional measures the proximity of the $N-q$ ($24 - 7 = 17$) smallest eigenvalues. In this case, a comparison of these eigenvalues illustrates the algorithm difficulty. The dashed line lies so close to the dotted line that the gradients involved in the computation of the update become small relative to the step size. A flat eigenvalue spectrum corresponds to a value of zero for the likelihood functional.

Figure 11. Eigenvalues of the STC

Table 2 shows the values of the likelihood functional for the various covariance structures. The magnitude of the likelihood functional directly relates to the size of the gradient and consequently to the convergence rate. While the first pass converged in about 10 iterations, attempts at modifying the step size for the second pass resulted in extremely slow convergence and, ultimately, algorithm failure.

Table 2. Values of Likelihood Functional for STC

	$L_q(\mathbf{Q}) = (N - q)(\ln(\bar{\lambda}_{GM}(q)) - \ln(\bar{\lambda}_{AM}(q)))$
$\mathbf{R} = \sigma_{DS}^2 \mathbf{P} + \sigma_{ES}^2 \mathbf{Q} + \sigma_0^2 \mathbf{I}_N$ (solid)	-0.5501
$\mathbf{R}_w = \mathbf{L}^{-1} \mathbf{R} \mathbf{L}^{-H}$ (dotted)	-0.0009442
$\mathbf{R} = \sigma_{DS}^2 \mathbf{P} + \sigma_0^2 \mathbf{I}_N$ (dashed)	0

To visualize the gradients involved, figure 12 depicts the likelihood functional of the STC as a function of the real and imaginary components of the primary AR coefficient. In this case, the

primary pole equals $-0.0044 - 0.6910i$, the maximum of the surface. Figure 13 represents a contour of the surface.

Figure 12. Likelihood Functional Surface for STC

Figure 13. Likelihood Functional Contour for STC

A second interpretation of the failure of the second pass of the algorithm relies on the magnitude of the AR coefficient for the second extended source. The magnitude of the coefficient equals 0.96, close to the unit circle. As the AR coefficient moves closer to the unit circle, the Gohberg formula produces an extended source covariance with extreme ill-conditioning due to a very strong principal eigenvalue. Essentially this type of covariance models a discrete source. The source contributes only to the principal eigenvalues of the covariance \mathbf{R} . In this manner, the pre-whitening eigenvalues that appear after the principal eigenvalues remain unaffected, contributing to a flat white eigenvalue spectrum.

CONCLUSIONS

The STC emphasizes certain deficiencies of the Le Cadre¹¹ prewhitening technique.* The presence of multiple extended sources that comprise the spatially colored noise results in the greatest difficulty. The great disparity in SNR between the two extended sources causes the algorithm to concentrate almost solely on the stronger source. After prewhitening the first strong source, a promotion of the weaker source occurs using MUSIC, although the noise eigenvalues represent nearly a white noise spectrum. A second pass of the prewhitener fails due to the nature of the prewhitened eigenvalues. Although the results are not presented here, inaccurate knowledge of the noise floor σ_0^2 diminishes algorithm performance substantially.

The estimate of the number of sources present in the acoustic field also greatly affects algorithm performance. Since many problems in sensor array processing rely on this estimate, research into its computation actively continues.

All optimization problems based on gradient algorithms suffer from inaccurate initialization and computation of suitable step size. Indeed, Le Cadre¹¹ presents a method for step size updating and provides the algorithm starting point. Other suitable techniques for optimization exist for this type of problem, notably the Broyden-Fletcher-Goldfarb-Shanno routines.²⁷

The parametric assumptions on the noise model restrict the utility of this approach to nonuniform arrays. The AR formulation fails when inaccurate sensor spacing or a curvature exists in the line array. Future work will attempt to address these inadequacies. Recent related research includes the work of Kay and Nagesha.^{28, 29}

* The MATLAB source code in this report will be provided to any interested party by electronic media.

APPENDIX A: COMPUTATION OF $\frac{\partial Q^1}{\partial a_i}$

(Omit all unnecessary indexing for simplicity.)

Define the N by N matrices Z^i such that

$$Z^i(j, k) = \begin{cases} 1 & \text{if } j - k = i \quad 1 \leq j \leq N \\ 0 & \text{else} \quad 1 \leq k \leq N \end{cases} \quad (\text{A-1})$$

Write the Toeplitz matrices A_1 and A_3 as

$$\begin{aligned} A_1 &= \sum_{i=0}^L a_i Z^i = a_0 I_N + \sum_{i=1}^L a_i Z^i, \\ A_3 &= \sum_{i=1}^L a_i Z^{N-i}. \end{aligned} \quad (\text{A-2})$$

To simplify the computation, formulate A_1 and A_3 in vector form:

$$\begin{aligned} A_1 &= a_0 I_N + [a_1 \ a_2 \ \dots \ a_L] \begin{bmatrix} Z^1 \\ Z^2 \\ \vdots \\ Z^L \end{bmatrix} \\ &= a_0 I_N + \bar{\mathbf{a}}^T \bar{\mathbf{Z}}_1, \end{aligned} \quad (\text{A-3})$$

$$\begin{aligned} A_3 &= [a_1 \ a_2 \ \dots \ a_L] \begin{bmatrix} Z^{N-1} \\ Z^{N-2} \\ \vdots \\ Z^{N-L} \end{bmatrix} \\ &= \bar{\mathbf{a}}^T \bar{\mathbf{Z}}_2, \end{aligned} \quad (\text{A-4})$$

where " $\bar{\cdot}$ " emphasizes a vector variable. Express the complex coefficients a_i as the sum of real and imaginary parts x_i and y_i so that

$$\begin{aligned} a_0 &= x_0 + jy_0, \\ \bar{a} &= \bar{x} + j\bar{y}, \end{aligned} \quad (\text{A-5})$$

where $j = \sqrt{-1}$. With the Gohberg formula formulate the matrix Q as

$$\begin{aligned} Q^{-1} &= \frac{1}{\sigma_{ES}^2} (A_1 A_1^H - A_3 A_3^H) \\ &= \frac{1}{\sigma_{ES}^2} \left(\left\{ (x_0 + jy_0)I_N + (\bar{x}^T + j\bar{y}^T)\bar{Z}_1 \right\} \left\{ (x_0 - jy_0)I_N + \bar{Z}_1^T(\bar{x} - j\bar{y}) \right\} \right. \\ &\quad \left. - \left\{ (\bar{x}^T + j\bar{y}^T)\bar{Z}_2 \right\} \left\{ \bar{Z}_2^T(\bar{x} - j\bar{y}) \right\} \right). \end{aligned} \quad (\text{A-6})$$

First compute the partial derivatives with respect to the zero-th coefficient:

$$\begin{aligned} \frac{\partial Q^{-1}}{\partial x_0} &= \frac{1}{\sigma_{ES}^2} \left[I_N \left\{ (x_0 - jy_0)I_N + \bar{Z}_1^T(\bar{x} - j\bar{y}) \right\} \right. \\ &\quad \left. + \left\{ (x_0 + jy_0)I_N + (\bar{x}^T + j\bar{y}^T)\bar{Z}_1 \right\} I_N \right], \\ &= \frac{1}{\sigma_{ES}^2} \left[2x_0 I_N + \bar{Z}_1^T(\bar{x} - j\bar{y}) + (\bar{x}^T + j\bar{y}^T)\bar{Z}_1 \right], \\ &= \frac{1}{\sigma_{ES}^2} [A_1 + A_1^H], \end{aligned} \quad (\text{A-7})$$

$$\begin{aligned} \frac{\partial Q^{-1}}{\partial y_0} &= \frac{1}{\sigma_{ES}^2} \left[jI_N \left\{ (x_0 - jy_0)I_N + \bar{Z}_1^T(\bar{x} - j\bar{y}) \right\} \right. \\ &\quad \left. + \left\{ (x_0 + jy_0)I_N + (\bar{x}^T + j\bar{y}^T)\bar{Z}_1 \right\} (-jI_N) \right], \\ &= \frac{j}{\sigma_{ES}^2} \left[(x_0 - jy_0)I_N + \bar{Z}_1^T(\bar{x} - j\bar{y}) - (x_0 + jy_0)I_N \right. \\ &\quad \left. - (\bar{x}^T + j\bar{y}^T)\bar{Z}_1 \right], \\ &= \frac{j}{\sigma_{ES}^2} [A_1^H - A_1]. \end{aligned} \quad (\text{A-8})$$

Define the complex gradient³⁰ as

$$\begin{aligned} \frac{\partial Q^{-1}}{\partial a_0} &= \frac{\partial Q^{-1}}{\partial x_0} + j \frac{\partial Q^{-1}}{\partial y_0} \\ &= \frac{2}{\sigma_{ES}^2} A_1. \end{aligned} \quad (\text{A-9})$$

Compute the partial derivatives with respect to the first through the Lth coefficients:

$$\begin{aligned} \frac{\partial Q^{-1}}{\partial \bar{x}} &= \frac{1}{\sigma_{ES}^2} \left[\begin{aligned} &\bar{Z}_1 \{ (x_0 - jy_0) I_N + \bar{Z}_1^T (\bar{x} - j\bar{y}) \} \\ &+ \{ (x_0 + jy_0) I_N + (\bar{x}^T + j\bar{y}^T) \bar{Z}_1 \} \bar{Z}_1 \\ &- \bar{Z}_2 (\bar{Z}_2^T (\bar{x} - j\bar{y})) - (\bar{x}^T + j\bar{y}^T) \bar{Z}_2 (\bar{Z}_2) \end{aligned} \right], \\ &= \frac{1}{\sigma_{ES}^2} [\bar{Z}_1 A_1^H + A_1 \bar{Z}_1 - \bar{Z}_2 A_3^H - A_3 \bar{Z}_2], \end{aligned} \quad (A-10)$$

$$\begin{aligned} \frac{\partial Q^{-1}}{\partial \bar{y}} &= \frac{1}{\sigma_{ES}^2} [j\bar{Z}_1 A_1^H - jA_1 \bar{Z}_1 - j\bar{Z}_2 A_3^H + jA_3 \bar{Z}_2], \\ &= \frac{j}{\sigma_{ES}^2} [\bar{Z}_1 A_1^H - A_1 \bar{Z}_1 - \bar{Z}_2 A_3^H + A_3 \bar{Z}_2], \end{aligned} \quad (A-11)$$

$$\begin{aligned} \frac{\partial Q^{-1}}{\partial \bar{a}} &= \frac{\partial Q^{-1}}{\partial \bar{x}^T} + j \frac{\partial Q^{-1}}{\partial \bar{y}^T}, \\ &= \frac{2}{\sigma_{ES}^2} [A_1 \bar{Z}_1^T - A_3 \bar{Z}_2^T]. \end{aligned} \quad (A-12)$$

The expressions in equations (A-10) - (A-13) also correctly compute the partial of the zero-th coefficient since

$$Z^0 = I_N \quad (A-13)$$

and

$$Z^N = 0_N. \quad (A-14)$$
